

## Survey

1. The first survey I found was on a website. It asked you to answer questions to see if you could have ADHD. The survey tried to give you a percentage of the possibility of you having ADHD based on your answers. The question was, what would you do under pressure? Are you an organized person with a routine? The target audience is the general public. The survey asked 25 multiple-choice questions.

## Reflection

While searching for surveys, I couldn't find one from a scholarly website, so I looked into different ones on ADHD and Screen time. Both of the surveys asked very different questions. The first survey was on ADHD. It was a very long survey, and the answers ranged from strongly disagree to agree strongly. They want to know your feelings about interacting with people in different conversations. My second survey was about how you feel and how screen time affects your mental and physical health. This survey was very different from the first one. This survey was very short and had open-ended and multiple answers, some with numbers and others about the devices you use. The survey aims to help you and others understand what affects them. Their answers can be used to help researchers develop an understanding of people.
